

Evidence from 266 studies

- Random CV exceeded an independent test by 0.15 on average; spatial CV by only 0.03.
- LOO and out-of-bag estimates gave the largest gap ($\Delta R^2 = 0.38$); avoid them as the baseline.
- Blocks sized with the semivariogram range measured a gap about 2.7 times larger (0.40 vs 0.15).
- The number of folds (5 or 10) and the split (70/30 or 80/20) did not change the gap.

Always report: sampling design · block or buffer size and how it was chosen · autocorrelation range · uncertainty of the CV estimate · an independent probability sample when the accuracy of the whole map matters.
